

Buck Regulator, Synchronous, 3.33 MHz, 1 A

FAN53745

WLCSP6
CASE 567WU

Description

The FAN53745 is a low quiescent current step-down DC/DC converter that delivers a regulated output voltage from an input supply of 2.3 V to 5.5 V. The combination of built-in power transistors, synchronous rectification, and a tiny solution size make the device ideal for portable applications.

The converter normally operates in PWM Mode at a typical fixed-frequency of 3.33 MHz. At moderate and light loads, the device will transition into PFM Mode to maintain high efficiency and excellent transient response. Additionally, a low power Shutdown Mode reduces power consumption when the device is disabled.

The FAN53745 is available in 6-bump, 0.4 mm pitch, Wafer-Level Chip-Scale Package (WLCSP).

Features

- Proprietary Current Mode Architecture
- Wide Input Voltage Range: 2.3 V to 5.5 V
- 1 A Load Capability
- PFM / PWM Modes for High Efficiency
- I²C-compatible Interface
- Programmable Output Voltage: 0.9 V to 3.3 V
- Programmable Current Limit: 440 mA to 2090 mA
- Internal Soft-Start
- Protection Faults
(OT, Input UVLO, Output Short and Reverse Current)
- Automatic Pass-Through Operation
- Hardware Reset when Holding SCL Low
- Pb-Free and RoHS Compliant

Applications

- Smart Phones
- Smart Watch
- Health Monitoring
- Sensor Drive
- Energy Harvesting
- Utility and Safety Modules
- RF Modules

MARKING DIAGRAM

- 12 = Alphanumeric Device Code
(see Ordering Information for specific device marking)
- KK = Lot Run Number
- X = Alphanumeric Year Code
- Y = 2-Weeks Date Code
- Z = Assembly Plant Code

Figure 1. Typical Application

ORDERING INFORMATION

See detailed ordering and shipping information on page 2 of this data sheet.

FAN53745

ORDERING INFORMATION

Part Number	Device Marking	Output Voltage	Slave Address	Temperature Range	Package	Shipping [†]
FAN53745UC00X	MJ	2.5 V	7h'20	-40°C to +85°C	6-bump WLCSP, S/B 1.50 x 0.94	Tape & Reel
FAN53745UC01X	MK	2.0 V	7h'30			
FAN53745UC02X (In Development)	MM	2.6 V	7h'32			

[†]For information on tape and reel specifications, including part orientation and tape sizes, please refer to our Tape and Reel Packaging Specifications Brochure, BRD8011/D.

BLOCK DIAGRAM

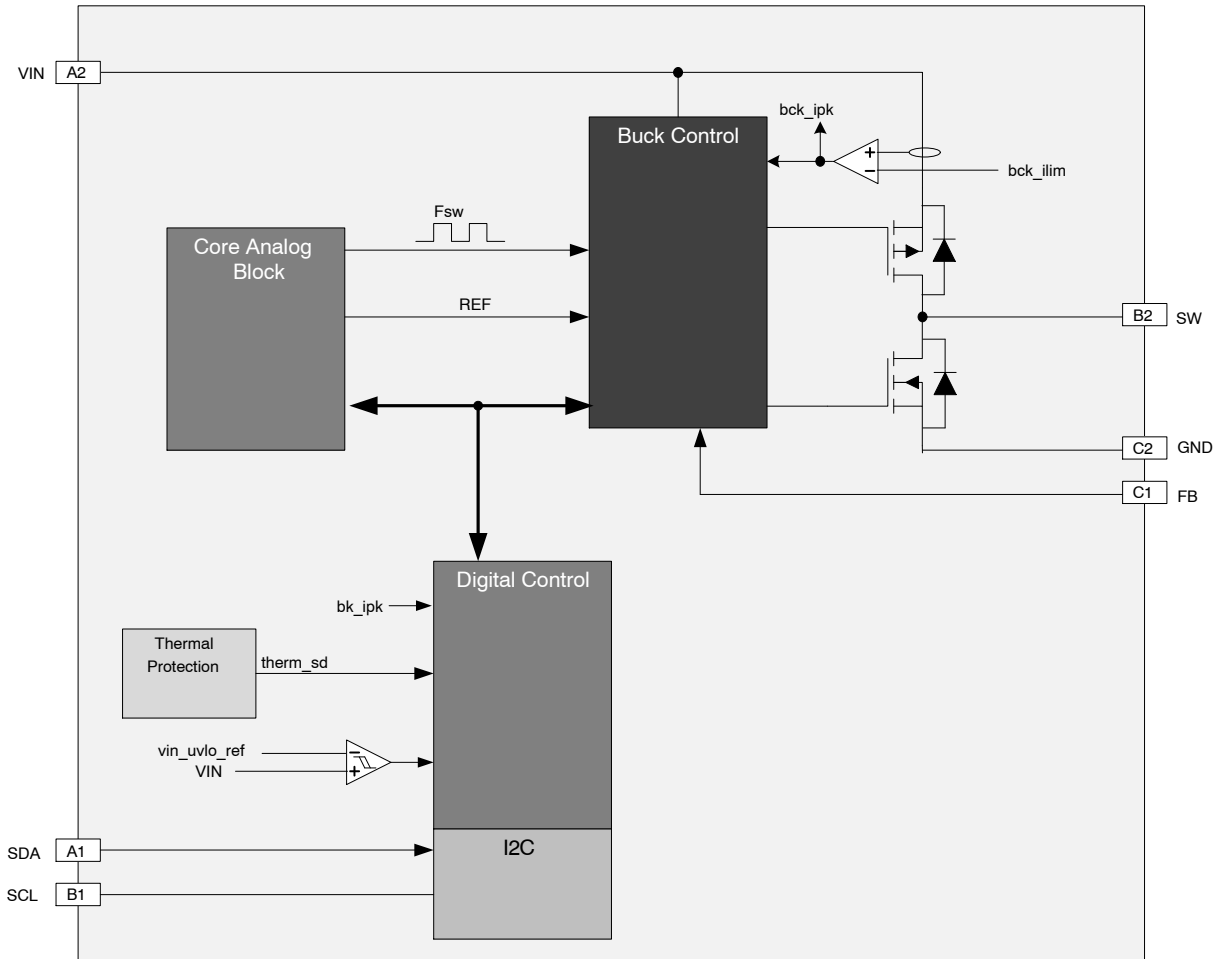

Figure 2. Block Diagram

PRODUCT PIN ASSIGNMENTS

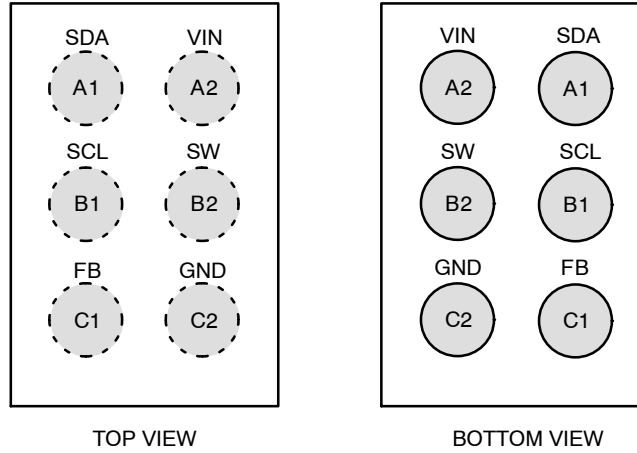

Figure 3. Pin Arrangement

PIN DESCRIPTION

Pin No.	Name	Description
A1	SDA	Serial Interface Data. I ² C input/output data line pin. Do not leave this pin floating.
A2	VIN	Input Voltage. Power input to converter. Place input decoupling capacitor as close to the this pin as possible.
B1	SCL	Serial Interface Clock. I ² C Clock input pin. Holding this pin low for 100 ms will generate a hardware reset. Do not leave this pin floating.
B2	SW	Switching Node. Connect to one side of the inductor.
C1	FB	Feedback. Connect to positive side of output capacitor.
C2	GND	Ground. Power and IC ground. All signals are referenced to this pin.

MAXIMUM RATINGS

Symbol	Parameter	Conditions	Min	Typ	Max	Unit
V _{IN}	Input Voltage		-0.3	-	6.0	V
V _{SW}	Voltage on SW Pin		-0.3	-	6.0	V
V _{CTRL}	SDA and SCL Pins		-0.3	-	(Note 1)	V
	FB Pin		-0.3	-	(Note 1)	V
ESD	Electrostatic Discharge Protection Level	Human Body Model	-	2.0	-	kV
ESD	Electrostatic Discharge Protection Level	Charged Device Model	-	500	-	V
T _J	Junction Temperature		-40	-	+150	°C
T _{STG}	Storage Temp		-40	-	+150	°C

Stresses exceeding those listed in the Maximum Ratings table may damage the device. If any of these limits are exceeded, device functionality should not be assumed, damage may occur and reliability may be affected.

1. Lesser of 6 V or V_{IN} + 0.3 V.

THERMAL CHARACTERISTICS (Note 2)

Symbol	Parameter	Conditions	Min	Typ	Max	Unit
Q _{JA}	Junction-to-Ambient Thermal Resistance		-	65	-	°C/W

2. Junction-to-ambient thermal resistance is a function of application and board layout. This data is measured with two-layer 2s2p with VIAs boards in accordance to JEDEC standard JESD51. Special attention must be paid not to exceed junction temperature T_J(max) at a given ambient temperature T_A.

RECOMMENDED OPERATING CONDITIONS

Symbol	Parameter	Conditions	Min	Typ	Max	Unit
V _{IN}	Supply Voltage Range		2.3	-	5.5	V
L	Inductor		-	0.47	-	μH
C _{IN}	Input Capacitor		-	4.7	-	μF
C _{OUT}	Output Capacitor		-	2x10	-	μF
I _{OUT}	Output Current		-	-	1000	mA
T _A	Operating Ambient Temperature		-40	-	+85	°C
T _J	Junction Temperature		-40	-	+125	°C

Functional operation above the stresses listed in the Recommended Operating Ranges is not implied. Extended exposure to stresses beyond the Recommended Operating Ranges limits may affect device reliability.

FAN53745

ELECTRICAL CHARACTERISTICS (Minimum and maximum values are at $V_{IN} = 3.8\text{ V}$, $V_{OUT} = 0.9\text{ to }3.3\text{ V}$, $T_A = -40^\circ\text{C to }+85^\circ\text{C}$ unless otherwise noted. Typical values are at $T_A = 25^\circ\text{C}$, $V_{IN} = 3.8\text{ V}$, $V_{OUT} = 2.6\text{ V}$)

Symbol	Parameter	Test Condition	Min	Typ	Max	Unit

FUNCTIONAL SPECIFICATIONS

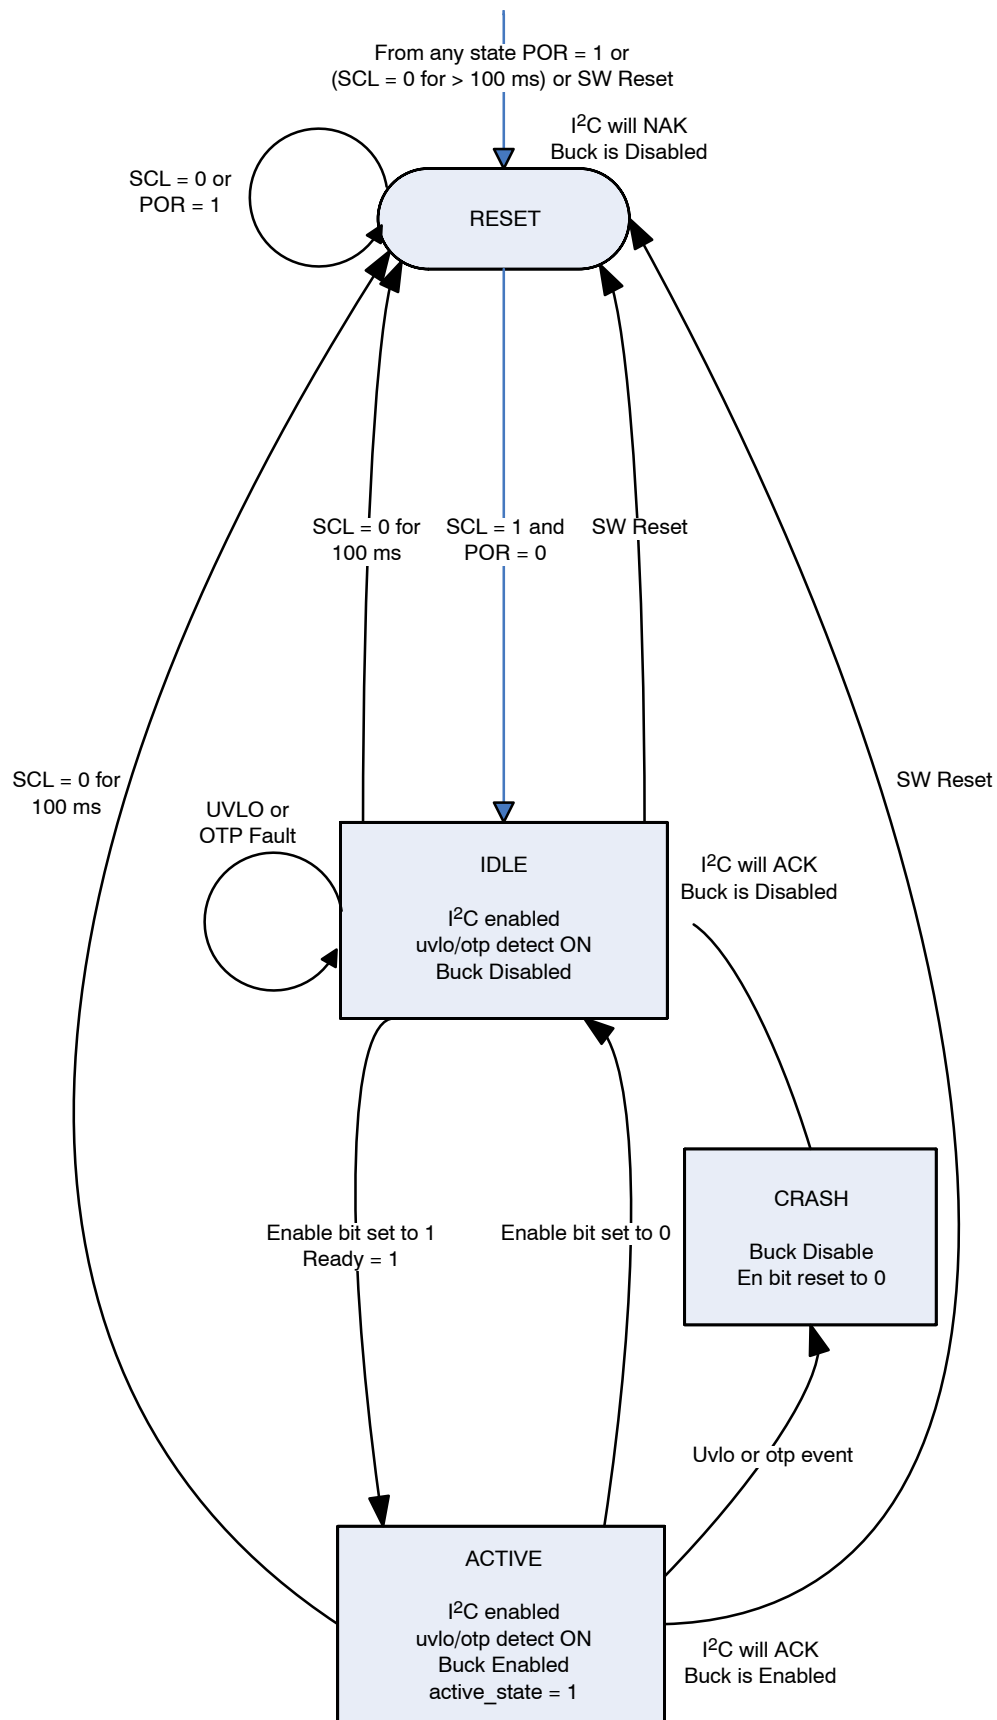

Device Operation

Operation Description

The FAN53745 uses a proprietary current mode architecture with synchronous rectification to convert input voltages down to a regulated output voltage while limiting the peak inductor current.

During medium to heavy loading of the output, the FAN53745 operates in PWM operation to ensure excellent regulation. During light loading, the device automatically switches to PFM operation for high efficiency. To avoid potential noise interference by PFM switching frequencies with the load or other circuitry, the device can be programmed into Forced PWM operation. More details on PFM and PWM operation can be found under the Modes of Operation heading.

FAN53745

Ready status = ((idle_state or active_state) and pwr_ok and (over_temp_fault or uvlo_fault))

Figure 33. State Diagram

Device States

Reset State

When power is applied to the FAN53745, the device will go through a Power On Reset (POR) and then the FAN53745 checks the state of the I²C SCL pin. If the SCL pin is low, the device will stay in the Reset State. If the SCL is high or if it at anytime goes high, the device moves to the Idle State. During Reset State, all I²C registers are cleared to their default values and cannot be written to or read. If at anytime the input voltage were to fall below the POR threshold, the device will completely power off.

Software Reset

If the correct Reset code is written to the RESET register or the SCL pin is pulled low for more than 100 ms, the device will exit the present state (Active or Idle) and enter the Reset State. For a SW reset, by setting the Reset register, the device will only enter the Reset State momentarily to clear the registers and then the device will enter Idle State.

SCL Low Reset

If the device entered Reset because the SCL was held low for more than 100 ms, house keeping circuitry will be powered down to reduce power consumption and all registers will be reset to their default values. The device will remain in the Reset State as long as the SCL is held low. Once the SCL is released high, a wait time of ~20 μ s or more should be allowed for the I²C to properly read any I²C commands. After the housekeeping circuitry is stable, the READY bit will be set and the ENABLE bit can be set for the device to move from the Idle State to Active State.

Note: Care should be used when sharing the I²C with another slave which may stretch the clock for more than 100 ms. If the application requires for the FAN53745 to ignore the SCL being held low, please consult your local On Semiconductor representative.

Idle State

In Idle State the I²C registers are read/write accessible and the UVLO comparator is activated. The READY bit in the Status Register 0x02h will be "1" while in the Idle State, providing there isn't a UVLO or OT fault. If the input voltage is less than UVLO rising threshold upon entering the Idle State from the Reset State, a UVLO fault will be generated and the device will stay in this state as long as $POR < VIN < UVLO$ rising.

When the device enters Idle State due to either a UVLO or OT condition, the device waits 20 ms for the fault to clear. If the fault still exists after the 20 ms, the device will remain in the Idle State and READY = 0 until the fault clears. If the ENABLE bit is set to a "1" while either a UVLO or OT fault condition exists, the bit will be immediately cleared and the device will not advance to the Active State. Only after the fault has cleared and ENABLE is then set to "1" will the device move to the Active State.

Active State

In Active State, the buck converter is enabled and provides a regulated output voltage to the load. If during Active State the input voltage falls between POR and UVLO_Falling, the device will exit Active State, the Enable bit will be cleared and the device will return to an Idle State.

If the device temperature exceeds the OTP threshold while in the Active State, the Enable bit will be cleared and the device will return to the Idle State. The device will remain in the idle state until it cools below the hysteresis level and the ENABLE bit is set again to "1".

When a UVLO or OTP fault occurs, the associated STATUS and FAULT register bits are set. The Status bit will be cleared when the input voltage recovers or the die temperature returns below the hysteresis level. The Fault bits will remain set to "1" until they are read.

Startup Behavior

Startup Description

To enable the FAN53745, the ENABLE Register bit must be set to “1”. The FAN53745 has internal soft-start which limits the input current from the battery by incrementing the voltage up to the target output voltage. This limits the current drawn and prevents brown out conditions. The device starts up within 520 μ s typical using the recommended external components table.

Shutdown Behavior

Disable

To disable the FAN53745, the ENABLE reg bit should be configured to code 0. When the part is disabled, the output will tristate. If the DISCHARGE SEL bits are set to something other than “00”, the output will be discharged through the selected resistance. Otherwise, if DISCHARGE SEL = “00”, the output will only be discharged by the load.

Active Pull Down

The FAN53745 has an active pull down to discharge the output capacitance. Once the ENABLE reg bit is set to 0, within $\sim 2 \mu$ s, the active pull down is enabled and discharges the VOUT via an internal resistor. The strength of the pull down can be selected between 50 Ω , 100 Ω (Default), 200 Ω and open by setting the DISCHARGE SEL I²C bit. If the DISCHARGE I²C bit is set to 1, the resistor selected by DISCHARGE SEL will be used to discharge the output during voltage programming transitions from a higher to lower voltage.

Modes of Operation

PFM

Pulsed Frequency Modulation (PFM) operation adjusts the switching frequency relative to the load. By reducing the switching frequency at lighter load conditions, higher efficiency is realized at these light loads. In Automode operation, the device enters PFM mode when the load falls below IPFM threshold.

PWM

During Pulse Width Modulation (PWM) mode, the device switches at a nominal fixed frequency of 3.3 MHz, which reduces the values of the external components. During Auto Mode, the part enters PWM when load currents exceed IPWM typ. In PWM mode the device has excellent load regulation, ideal for powering loads which are sensitive to deviations in supply voltage. The FAN53745 can be forced into PWM (FPWM) regardless of the load current by setting FORCE_PWM to a “1”.

Pass Thru

To ensure there is not sub-harmonic behavior when Vin is close to the Vout_Target, the device enters Pass-Thru automatically. Using a proprietary method, the device maintains excellent regulation when transitioning into and out of Pass-Thru mode.

Protection Features

SHORT FAULT

If the output voltage falls below one-half the programmed voltage during normal operation, the device will declare a Short fault immediately without a debounce period and the SHORT FAULT bit will be set.

PFM Current Limit

During PFM operation, the peak current is limited to control the ripple and prevent the inductor from saturating. The open loop PFM current limit can be programmed between 500 mA and 1325 mA in 55 mA steps. Due to inherent delays, the closed loop PFM current limit is expected to be 10 to 15% higher than the open loop PFM ILIMIT threshold of the device. Once the current limit is set, it can be locked by setting the locking bit V_I_LIMIT_LOCK.

PWM Current Limit

A heavy load or short circuit on the output causes the current in the inductor to increase until a maximum current threshold is reached in the high-side switch. Upon reaching this point, the high-side switch turns off, preventing high currents from damaging the device. After 500 μ s of current limit, the regulator triggers an over-current fault, causing the regulator to shut down for about 20 ms before attempting a restart. If the fault is caused by a short circuit, the soft-start circuit attempts to restart after about 20 ms and produces a SHORT FAULT if the fault persisted.

The open Loop Peak Inductor Current Limit can be programmed via I²C and range from 440 mA to 2090 mA max in 110 mA steps. Due to inherent delays, the closed loop current limit is expected to be 10 to 15% higher than the open loop ILIMIT threshold of the device.

UVLO

• Rising

While in Idle or Active State, the UVLO detection is enabled. The FAN53745 is designed to check the input voltage before enabling the converter. For Idle State, the input voltage must be above the UVLO rising threshold when the ENABLE bit is set to enable the buck converter. Otherwise, once loaded by the buck converter, the input voltage may fall below the UVLO falling threshold, resulting in start-up hiccup behavior. If the voltage is below the UVLO rising threshold when the ENABLE bit is set, the UVLO fault and status bits will be set and the ENABLE bit cleared.

• Falling

If the input voltage falls below the UVLO_falling threshold during Active State, the buck ENABLE bit will be cleared, the device will go to the Idle State and the PASS-THRU and PFM-PWM bits in the Status Reg are set to their default values of “0” and “1” respectively.

Thermal Shutdown

When the die temperature increases, due to a high load condition and/or a high ambient temperature, the ENABLE bit is cleared and the device returns to Idle State and the OVER_TEMP Status and Fault bits are set. The PASS-THRU and PFM-PWM bits in the Status Reg are set to their default values of "0" and "1" respectively.

By monitoring the OVER_TEMP bit in the FAULT STATUS register, when the die temperature falls below the hysteresis temperature and OVER_TEMP falls to "0", the buck can be re-enabled.

Negative Current Limit

The FAN53745 has a negative current limit protection which limits the current through the NFET in PWM Mode. If a voltage is applied to the buck output and is higher than VOUT target while in PWM, a negative current will be detected. Once the inductor current hits -1 A for one cycle, the output begins to tristate until the applied voltage is released and the output voltage falls below the regulated voltage.

In PFM mode, the Zero Crossing Detection does not allow any negative current to flow within inductor, any voltage higher than vout target applied to output will cause the regulator to enter tri-state and block current back through inductor.

NOTE: If a voltage applied to VOUT is greater than VIN, the body diode of high side FET will conduct.

Output Voltage*Programmable Output Voltage*

The FAN53745 output voltage can be programmed in 10 mV steps from 1.5 to 3.3 V using the VESL register. The voltage transition is implemented by stepping through the voltage programming DAC up-to/down-to the new target voltage. The FAN53745 provides DVS functionality where

by the period of time between each step can be controlled by setting the DVS register bits.

Limiting the Programmable Range

If a new voltage value is written into the VSEL register which is either lower than VMIN or higher than VMAX, the DAC will scale but the value will not be programmed. The output voltage will remain at the present value.

If a new value for VMIN or VMAX is written to the registers and is either higher than or lower than respectively of the present voltage in the VSEL register, the output voltage will remain at its present value until programmed to a valid VSEL value.

Dynamic Voltage Scaling

The FAN53745 DVS operation for programming the voltage to a new level can be controlled by setting the DVS register bits for rates of 0.5 to 10 mV/μs. If the DVS EN bit in the MODE Register, 0x03 is set to a "1" when the output voltage is commanded to a lower voltage, the DAC decrements through the programmable output voltage steps until the reference value for target voltage is reached. The output voltage will fall at a rate dependent on the amount of distributed capacitance and load. The speed of the reduction in voltage can be accelerated by setting the DISCHARGE register bit in the SHUTDOWN register. The discharge resistance will be disabled when the DAC reference value is reached. The drawings below provide an example of the behavior during rising and falling DVS control.

Note:

- If there is little or no load on the output during the ramp, some non-linear ramping of the output voltage may be observed during DVS ramping.
- Simply setting the DVS bit to a "1" does not initiate voltage change. Voltage change is only initiated when the VSEL register value is changed.

I²C Interface

Introduction

The FAN53745 serial interface is compatible with the Standard-mode, Fast-mode and Fast-mode Plus I²C bus specifications. The SCL pin is an input and the SDA pin is bi-directional with an open-drain output configuration. The

IC supports single register read and write transactions as well as multiple register read transactions.

Slave Address

The default I²C address for one of the device options is shown below. See Ordering Information for the other released device options and their default values. Contact **onsemi** to request configuration options.

Table 1. DEVICE ADDRESS VALUES

Device	Hex	Binary
FAN53745UC00X	7h20	0100000X

Table 2. 7-BIT BINARY ADDRESS

7	6	5	4	3	2	1	X

WRITE = 0

I²C Timing Diagrams

Figure 34. I²C Interface Timing for Fast-Mode Plus, Fast-Mode and Standard-Mode

Normally, data transfer occurs when the SCL is LOW. Data is clocked in on the rising edge of SCL. Typically data transitions at or after the subsequent falling edge of SCL to

provide ample setup time for the next data bit to be ready before the subsequent rising edge of the SCL.

Figure 35. Data Transfer Timing

The idle state of I²C bus is with both SCL and SDA HIGH. Each bus transaction begins and ends with SDA and SCL HIGH. A transaction begins with a START condition, which

is defined as SDA transitioning from High to LOW with SCL HIGH.

Figure 36. Start Bit Timing

A valid transaction ends with a STOP condition which occurs when SDA transitions from LOW to HIGH while SCL remains HIGH.

Figure 37. Stop Bit Timing

A REPEATED START condition is functionally equivalent to a STOP condition followed by a START condition. During a read from the IC, the master issues a REPEATED START after sending the register address and

before re-sending the slave address. The REPEATED START is a HIGH to LOW transition on SDA while SCL is HIGH.

Figure 38. Repeated Start Timing

Read and Write Transactions

Figure 39. Single Register Write Transaction

Figure 40. Single Register Read Transaction

Figure 41. Multiple Register Write Transaction

I²C Hardware Reset

The FAN53745 can be reset and the I²C registers cleared to their default values by pulling SCL low for more than 100 ms.

Figure 42. I²C Timing

FUNCTIONAL BEHAVIOR

Defined Behavior

PFM \leftrightarrow PWM Thresholds

Device will transition into PWM when IOU_T reaches IPWM and transition back to PFM when load current falls below IPFM.

Bit	Name	Default	Type	Description	
7:5	UNUSED				
4	STARTUP TIMEOUT FAULT	0	R/CLR	Displays startup timeout fault status. This indicator is latched when startup timeout occurs and causes a fault. The flag is cleared upon read.	
				Code	Start Up Time-Out Fault
				0	No startup timeout fault occurred
				1	A startup timeout fault occurred
3	UVLO FAULT	0	R/CLR	Displays UVLO fault status. This indicator is latched when UVLO occurs and causes a fault. The flag is cleared upon read.	
				Code	Under Voltage Fault Occurance
				0	No UVLO fault occurred
				1	A UVLO fault occurred
2	OVER TEMP FAULT	0	R/CLR	Displays over temp fault status. This indicator is latched when over temp occurs and causes a fault. The flag is cleared upon read.	
				Code	Start Up Time-Out Fault
				0	No over temp fault
				1	An over temp fault occurred
1	SHORT FAULT	0	R/CLR	Displays Vout short fault status. This indicator is latched when Vout short occurs and causes a fault. The flag is cleared upon read.	
				Code	Vout Short Fault
				0	The output has not shorted
				1	The output was shorted
0	ILIM FAULT	0	R/CLR	During PWM operation, if the peak current limit is hit continuously for 500 μ s, a fault is generated. The flag is cleared upon read.	
				Code	Vout Short Fault
				0	The output has not shorted
				1	The output was shorted

Table 6. REGISTER DETAILS – 0X02 STATUS

0x02 STATUS				Default = 00010000	
Bit	Name	Default	Type	Description	
7	UNUSED				
6	READY	0	Read	Reset condition: 0	
				Code	DEVICE READY
				0	Indicates that either the device is not in Idle mode or that there is a UVLO or over temperature fault.
				1	Indicates that the device is in IDLE mode; that the input voltage is good and the die temperature is within safe operating range.
5	PASS-THRU OPERATION	0	Read	Reset condition: 0	
				The Pass-Thru Operation bit gives the status of the converter.	
				Code	State of Operation
				0	Converter functioning in PFM or PWM operation.
4	PFM_PWM	1	Read	Reset condition: 0	
				This bit indicates the device is operating in PFM mode or PWM mode.	
				Code	PFM or PWM Switching
				0	PFM operation
3	UVLO	0	Read	Displays UVLO comparator status.	
				Code	UVLO Status
				0	Input voltage is good
				1	The input voltage is presently below the UVLO threshold
2	OVER TEMP	0	Read	Displays over temp comparator status.	
				Code	Die Temperature Status
				0	The die temperature is safe for operation
				1	The die is too hot to operate
1	VOUT SHORT	0	Read	Displays Vout short comparator status.	
				Code	Output Shorted
				0	No Vout short fault
				1	The output is presently shorted or is in a state of recovery after a short
				This bit will be cleared when the buck is disabled.	
0	CURRENT LIMIT	0	Read	Displays over current comparator status.	
				Code	Current Limit Detect
				0	No over current fault
				1	The buck converter is presently hitting peak current limit

Table 7. REGISTER DETAILS – 0X03 MODE

0x03 MODE				Default = 00011111	
Bit	Name	Default	Type	Description	
7	ENABLE2	0	R/W	This register enables/disables the buck regulator. Setting a code 0 shutdowns the device, where as code 1 enables the device.	
				Code	Effect
				0	Buck Converter disabled
				1	Buck Converter enabled
6	FORCE_PWM	0	R/W	Forces the part to operate in PWM mode regardless of the load current.	
				Code	Mode
				0	Auto (PFM/PWM depending on load current)
				1	Force PWM
5	V_I_LIMIT_LOCK	0	R/W	Reset condition: 0	
				Code	LOCK
				0	VMIN, VMAX, PFM and PWM Ilimit levels are not locked.
				1	Locks the minimum (VMIN), Maximum(VMAX) voltages and PFM and PWM current limits that the device can be programmed to.
4	SS TIMEOUT	1	R/W	This register activates/deactivates the soft start time-out timer.	
				Code	Status of Soft Start Timer
				0	The converter will continuous attempt to reach output regulation.
				1	A timer is activated when the converter is enabled. If the converter output fails to reach regulation in 2ms, a fault will be declared.
3	DVS EN	1	R/W	Reset condition: 0	
				This register bit enables/disables the DVS functionality	
				Code	DVS Enable
				0	DVS operation is disabled
2:0	DVS	111	R/W	Reset condition: 0	
				DVS rate control register bits	
				Code	Voltage Scaling Rate
				000	0.5 mV/μs
				001	1.0 mV/μs
				010	1.5 mV/μs
				011	2.0 mV/μs
				100	2.5 mV/μs
				101	3.5 mV/μs
				110	5.0 mV/μs
				111	10 mV/μs

0x09 RESET				Default = 00000000	
Bit	Name	Default	Type	Description	
7:0	SOFT_RESET	00000000	Write	The software reset register allows all I ² C settings to be reverted to POR defaults when 0x45h code is written to it.	

APPLICATION GUIDELINES

Table 14. PRIMARY COMPONENTS

Component	Manufacturer	Part Number	Description	Case Size	Voltage Rating
CIN	Murata	GRM035R60J475ME15D	4.7 μ F	0201/0603 (0.6 mm x 0.3 mm)	6.3 V
L	Samsung	CIGT201208EHR47MNE	0.47 μ H $I_{SAT} = 4.3$ A $I_{RAT} = 3.9$ A $R_{DC} = 31$ Ω	0805/2012 (2 mm x 1.2 mm)	–
COUT	Murata	GRM155R60J106ME47D	2x 10 μ F	0402/1005 (1.0 mm x 0.5 mm)	6.3 V

Input Capacitor Considerations

The 2.2 μ F ceramic 0402 (1005 metric) input capacitor should be placed as close as possible between the VIN pin and GND to minimize the parasitic inductance. If a long wire is used to bring power to the IC, additional “bulk” capacitance (electrolytic or tantalum) should be placed between CIN and the power source lead to reduce the ringing that can occur between the inductance of the power source leads and CIN.

The effective capacitance value decreases as VIN increases due to DC bias effects.

Inductor Considerations

The output inductor must meet both the required inductance and the energy-handling capability of the application. The inductor value affects average current limit, the PWM-to-PFM transition point, output voltage ripple, and efficiency.

The ripple current (ΔI) of the regulator is:

$$\Delta I \approx (V_{OUT}/V_{IN}) \cdot ((V_{IN} - V_{OUT}) / (L \cdot f_{sw})) \quad (\text{eq. 1})$$

The maximum average load current, $I_{MAX(LOAD)}$, is related to the peak current limit, $I_{LIM(PK)}$, by the ripple current, given by:

$$I_{MAX(LOAD)} = I_{LIM(PK)} - \Delta I/2 \quad (\text{eq. 2})$$

The FAN53745 is optimized for operation with $L = 0.47$ μ H. The inductor should be rated to maintain at

least 80% of its value at $I_{LIM(PK)}$. It is recommended to select an inductor where its saturation current is above the $I_{LIM(PK)}$ value.

Efficiency is affected by the inductor DCR and inductance value. Decreasing the inductor value for a given physical size typically decreases the DCR; but because ΔI increases, the RMS current increases, as do the core and skin effect losses.

$$I_{RMS} = \text{SQRT} (I_{OUT(DC)}^2 + \Delta I^2/12) \quad (\text{eq. 3})$$

The increased RMS current produces higher losses through the $R_{DS(ON)}$ of the IC MOSFETs, as well as the inductor DCR. Increasing the inductor value produces lower RMS currents, but degrades transient response. For a given physical inductor size, increased inductance usually results in an inductor with lower saturation current and higher DCR.

Output Capacitor Considerations

FAN53745 uses two 10 μ F 0402 (1005 metric) for an output capacitor. The effective capacitor of ceramic capacitors decrease as the bias voltage increases. To overcome this increasing the output capacitor has no effect on loop stability and therefore the COUT can be increased to reduce the output voltage ripple or to improve transient response. Output voltage ripple is defined as:

$$\Delta V_{OUT} = \Delta I_L \cdot [(f_{SW} \cdot C_{OUT} \cdot ESR^2/(2 \cdot D \cdot (1 - D))) + (1/(8 \cdot f_{SW} \cdot C_{OUT}))] \quad (\text{eq. 4})$$

Recommended Layout

NOTES
 CIN = 0201 = 0.6mm x 0.3mm
 L = 2012 = 2mm x 1.25mm
 COUT = 0402 = 1mm x 0.5mm
 Fan53745 = 1.5mm x 0.94mm

Layout Guideline
 The Recommended Component placement and routing is illustrated below. Components are placed on the top PCB layer with top copper routing shown in RED. The SW pin is routed directly to L1 using Mid-Layer_1 with copper routing shown in BLUE.
 For thermal reasons, it is recommended to maximize the pour area for all planes other than SW. The ground pour should be set to fill all available PCB surface area, and tied to internal layers with a cluster of thermal via.

Figure 43. Recommended Placement

Layout Considerations

To minimize spikes at V_{OUT} , C_{OUT} must be placed as close as possible to P_{GND} and V_{OUT} , as shown in

For thermal reasons, it is suggested to maximize the pour area for all planes other than SW. Especially the ground pour should be set to fill all available PCB surface area and tied to internal layers with a cluster of thermal via.
