

## High power white LED driver with I<sup>2</sup>C interface

### Features

- Buck-boost DC/DC converter
- Drives one power white LED up to:  
800 mA between 3.3 V to 5.5 V  
600 mA between 2.7 V to 5.5 V
- Efficiency up to 92%
- Output current control
- 1.8 MHz typ fixed frequency PWM
- Synchronous rectification
- Full I<sup>2</sup>C control
- Operational modes:  
Shutdown mode
- Ready mode + auxiliary red LED  
Ready mode + NTC  
Flash mode: up to 800 mA  
Torch mode: up to 200 mA
- Soft and hard triggering of flash
- Flash and torch dimming with 16 exponential values
- Dimmable red LED indicator auxiliary output
- Internally or externally timed flash operation
- Digitally programmable safety time-out in flash mode
- LED overtemperature detection and protection with external NTC resistor
- Opened and shorted LED failure detection and protection
- Chip over temperature detection and protection
- < 1 µA Shutdown current
- Package (3x3 mm) TFBGA25

### Applications

- Cell phone and smart phones
- Camera flashes/strobe
- PDAs and digital still cameras

### Description

The STCF03I is a high efficiency power supply solution to drive a single flash LED in camera phone, PDAs and other hand-held devices. It is a buck - boost converter to guarantee a proper LED current control over all possible conditions of battery voltage and output voltage; the output current control ensures a good current regulation over the forward voltage spread characteristics of the flash LED.

Thanks to the high efficiency of the converter, the input current taken from the battery remains under 1.5 A. All the functions of the device are controlled through the I<sup>2</sup>C bus which helps to reduce logic pins on the package and to save PCB tracks on the board. (See [1: Description \(continued\)](#))

## 1 Description (continued)

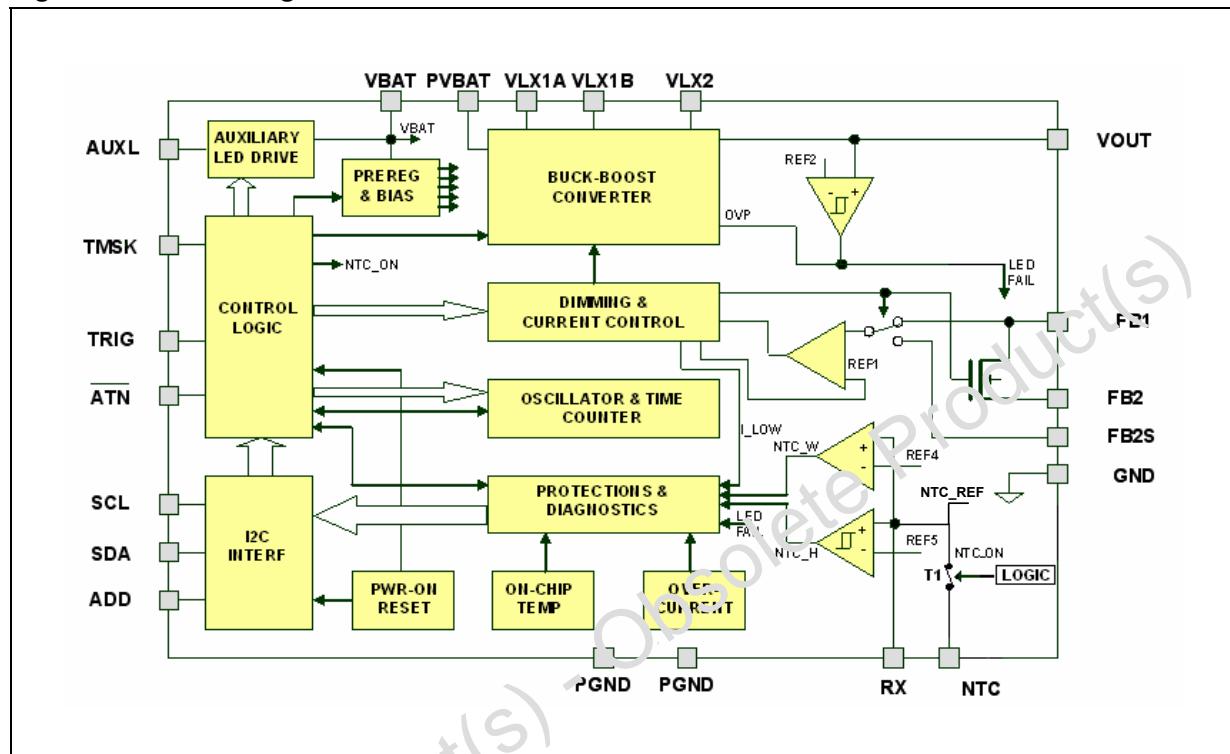

Hard and soft-triggering of flash are both supported. The device includes many functions to protect the chip and the power LED, such as: a soft start control, chip over temperature detection and protection, as well as opened and shorted LED detection and protection. Besides, a digital programmable time out function protects the LED in case of a wrong command from the µP. An optional external NTC resistor is supported to protect the LED against over heating. In mobile phone applications, it is possible to reduce immediately the flash LED current during the signal transmission using the TMSK pin. This saves battery life and gives more priority to supply RF transmission instead of flash function.

It is possible by I<sup>2</sup>C to separately program the current intensity in flash and torch mode using exponential steps. An auxiliary output can control an optional red LED to be used as a recording indicator.

The device is packaged in 3x3 mm µTFBGA25 with a height less than 1 mm.

E4	ATN	Attention (open drain output, active LOW)
E3	SDA	I <sup>2</sup> C data
C3,D3	PGND	Power ground
E5	SCL	I <sup>2</sup> C clock signal
C4	TRIG	Flash trigger input

## 4 Maximum ratings

**Table 3. Absolute maximum ratings (see Note:)**

Symbol	Parameter	Value	Unit
VBAT	Signal supply voltage	-0.3 to 6	V
PVBAT	Power supply voltage	-0.3 to 6	V
VLX1A, VLX1B	Inductor connection 1	-0.3 to $V_I+0.3$	V
VLX2	Inductor connection 2	-0.3 to $V_O+0.3$	V
VOUT	Output Voltage	-0.3 to 6	V
AUXL	Auxiliary LED	-0.3 to $V_I+0.3$	V
FB1, FB2, FB2S	Feedback and sense voltage	-0.3 to 3	V
SCL, SDA, TRIG, ATN, ADD TMSK	Logic pin	-0.3 to $V_I+0.3$	V
R <sub>X</sub>	Connection for reference resistor	-0.3 to 3	V
NTC	Connection for LED Temperature sensing	-0.3 to 3	V
ESD	Human body model	$\pm 2$	kV
P <sub>TOT</sub> (BGA) <sup>(1)</sup>	Continuous power dissipation (at $T_A=70^\circ\text{C}$ )	800	mW
T <sub>OP</sub>	Operating junction temperature range	-40 to 85	°C
T <sub>J</sub>	Junction temperature	-40 to 150	°C
T <sub>STG</sub>	Storage temperature range	-65 to 150	°C

1. Power dissipation is related parameter to used PCB. The recommended PCB design is included in the application note.

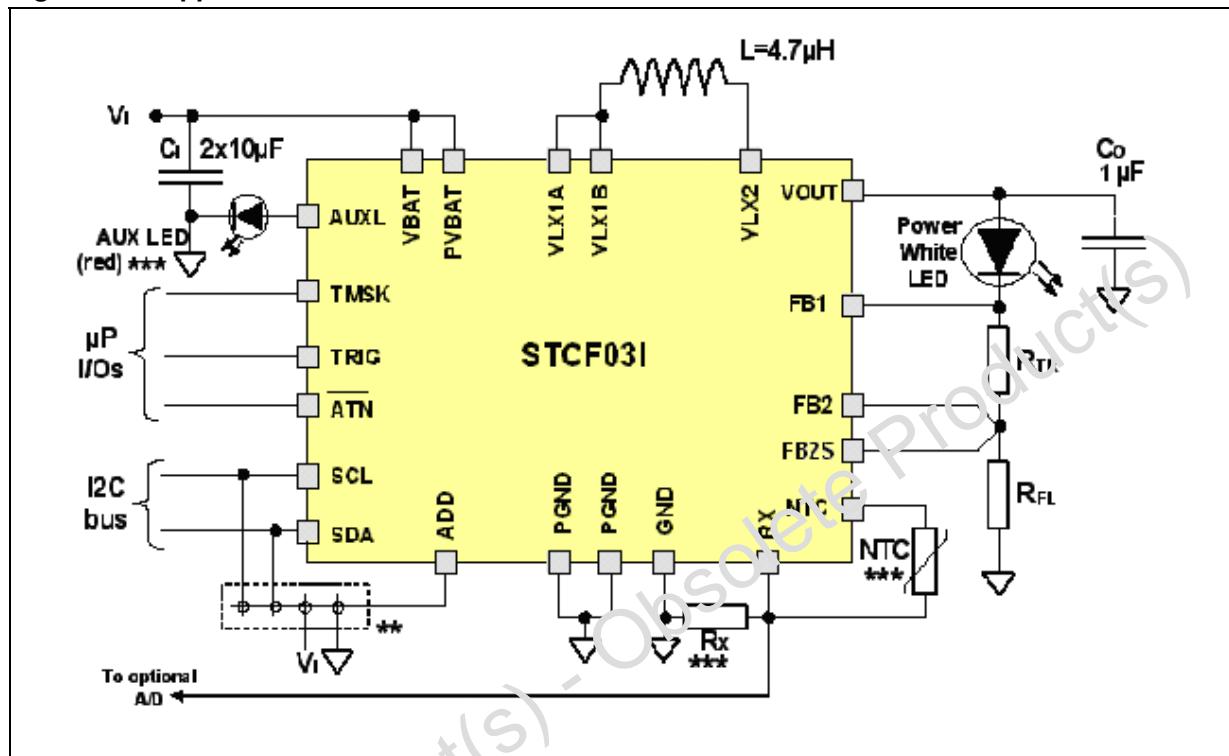

**Note:** *Absolute maximum ratings are those values beyond which damage to the device may occur. Functional operation under these condition is not implied.*

**Table 4 Thermal data**

Symbol	Parameter	Value	Unit
R <sub>thJA</sub>	Thermal resistance junction-ambient	150	°C/W

## 5 Application

Figure 3. Application schematic

\*\*: Connect to  $V_I$ , or  $GND$  or  $SDA$  or  $SCL$  to choose one of the 4 different I<sup>2</sup>C Slave Addresses.

\*\*\*: Optional components to support auxiliary functions.

Table 5. List of external components

Component	Manufacturer	Part number	Value	Size
$C_1$	TDK	X5R0J106M	$10\mu F$	0603
$C_0$	TDK	X5R0J105M	$1\mu F$	0603
$L$ ( $I_{FLASH} = 0.5A$ )	TDK	VLF3012ST-4R7MR91	$4.7\mu H$	$2.6 \times 2.8 \times 1.2$ mm
$L$ ( $I_{FLASH} = 0.8A$ )	TDK	VLF4012AT-4R7M1R1	$4.7\mu H$	$3.7 \times 3.5 \times 1.2$ mm
NTC	Murata	NCP21WF104J03RA	$100\text{ k}\Omega$	0805
$R_{FL}$			$0.27\Omega$	0603
$R_{TR}$			$1.8\Omega$	0402
$R_X$			$15\text{ k}\Omega$	0402
LED	Luxeon LED	LXCL-PW1		

Note: All of the above listed components refer to typical application. Operation of the STCF03I is not limited to the choice of these external components.

## 6 Electrical characteristics

Note: *Typical value, not production tested.*

## 7 Introduction

The STCF03I is a buck-boost converter, dedicated to power and control the current of a power white LED in a camera cell phone. The device operates at a constant switching frequency of 1.8 MHz typ. It provides an output voltage down to 2.5 V and up to 5.3 V, from a 2.7 V to 5.5 V supply voltage. This supply range allows operation from a single cell Lithium-Ion battery. The I<sup>2</sup>C bus is used to control the device operation and for diagnostic purposes. The current in torch mode is adjustable from 15 mA to 200 mA. Flash mode current is adjustable up to 800 mA for an input voltage ranging from 3.3 V to 5.5 V and up to 600 mA for an input voltage ranging from 2.7 V to 5.5 V. The Aux LED current can be adjusted from 0 to 20 mA. The device uses an external NTC resistor to sense the temperature of the white LED. These two last functions may not be needed in all applications, and in these cases the relevant external components can be omitted.

### 7.1 Buck-Boost converter

The regulation of the PWM controller is done by sensing the current of the LED through external sensing resistors ( $R_{FL}$  and  $R_{TR}$ , see application schematic). Depending on the forward voltage of the flash LED, the device automatically can change the operation mode between buck (step down) and boost (step up) mode.

Three cases can occur: Boost region ( $V_O > V_{BAT}$ ): this configuration is used in most cases, as the output voltage  $V_O = V_{FILED} + I_{LED} \times R_{FL}$  is higher than  $V_{BAT}$ ; Buck region ( $V_O < V_{BAT}$ ); Buck / Boost region ( $V_O \sim V_{BAT}$ ).

### 7.2 Logic pin description

#### 7.2.1 SCL, SDA pins

These are the standard clock and data pins as defined in the I<sup>2</sup>C bus specification. External pull up is required according to I<sup>2</sup>C bus specifications. The recommended maximum voltage of these signals should be 3.0 V.

#### 7.2.2 TRIG pin

This input pin is internally AND-ed with the TRIG\_EN bit to generate the internal signal that activates the flash operation. This gives to the user the possibility to accurately control the flash duration using a dedicated pin, avoiding the I<sup>2</sup>C bus latencies (hard-triggering). No internal pull-up nor pull-down is provided.

#### 7.2.3 ATN pin

This output pin (open-drain, active LOW) is provided to better manage the information transfer from the STCF03I to the µP. Because of the limitations of a single master I<sup>2</sup>C bus configuration, the µP should regularly poll the STCF03I to verify if certain operations have been completed, or to check diagnostic information. Alternatively, the µP can use the ATN pin to be advised that new data are available in the STAT\_REG, thus avoiding continuous polling. Then the information can be read in the STAT\_REG by a read operation via I<sup>2</sup>C that, besides, automatically resets the ATN pin. The STAT\_REG bits affecting the ATN pin status are mapped in [Table 16](#). No internal pull-up is provided.

## 7.2.4 ADD pin

With this pin it is possible to select one of the 4 possible I<sup>2</sup>C slave addresses. No internal pull-up nor pull-down is provided. The pin has to be connected to either GND, V<sub>I</sub>, SCL or SDA to select the desired I<sup>2</sup>C slave address (see [Table 7](#))

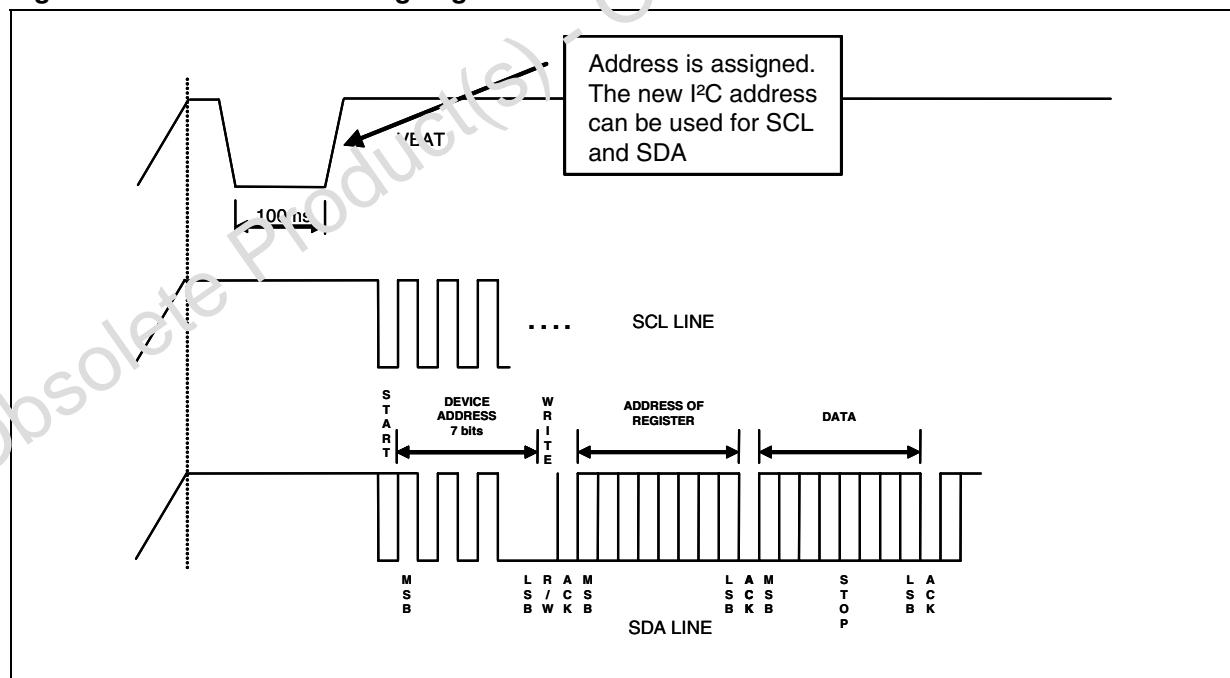

**Table 7. Address table**

ADD pin	A7	A6	A5	A4	A3	A2	A1	A0
GND	0	1	1	0	0	0	0	R/W
VBAT	0	1	1	0	0	0	1	R/W
SDAL	0	1	1	0	0	1	0	R/W
SCL	0	1	1	0	0	1	1	R/W

When ADD is connected to GND the I<sup>2</sup>C address is assigned automatically while in the other three configurations in which ADD pin is connected to VBAT or SDA or SCL, the following procedure must be activated in order that the right address is assigned.

After applying VBAT to the chip, the VBAT voltage must be pulled down to GND for a time longer than 100 ms. After that time the right I<sup>2</sup>C address is assigned to the chip. This procedure must be repeated every time the VBAT voltage is disconnected (see [Figure 4](#) below).

**Figure 4. Procedure for assigning a non-default I<sup>2</sup>C address**

## 7.2.5 TMSK pin

This pin can be used to implement the T<sub>X</sub> masking function. This function has effect only for flash current settings higher than 200 mA (bit FDIM\_3=1). Under this condition, when this pin is pulled high by the µP, the current flowing in the LED is forced at 200 mA typ. No internal pull-up nor pull-down is provided; to be externally wired to GND if T<sub>X</sub> masking function is not used.

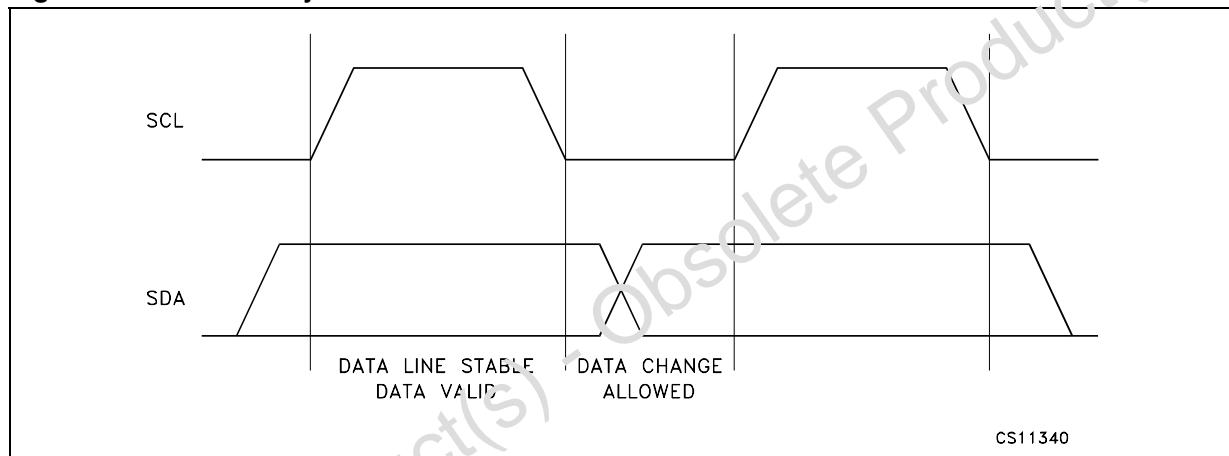

## 7.3 I<sup>2</sup>C bus interface

Data transmission from the main µP to STCF03I and vice versa takes place through the 2 I<sup>2</sup>C bus interface wires, consisting of the two lines SDA and SCL (pull-up resistors to a positive supply voltage must be externally connected). The recommended maximum voltage of these signals should be 3.0 V.

## 7.4 Data validity

As shown in *Figure 5*, the data on the SDA line must be stable during the high period of the clock. The HIGH and LOW state of the data line can only change when the clock signal on the SCL line is LOW.

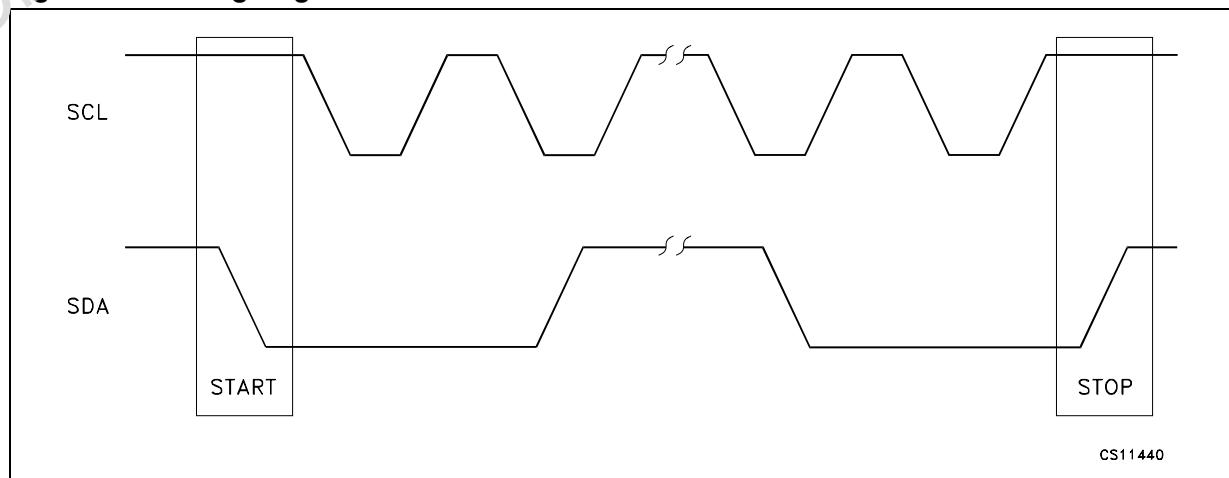

**Figure 5.** Data validity on the I<sup>2</sup>C Bus

## 7.5 Start and stop conditions

Both DATA and CLOCK lines remain HIGH when the bus is not busy. As shown in *Figure 6*, a start condition is a HIGH to LOW transition of the SDA line while SCL is HIGH. The stop condition is a LOW to HIGH transition of the SDA line while SCL is HIGH. A STOP condition must be sent before each START condition.

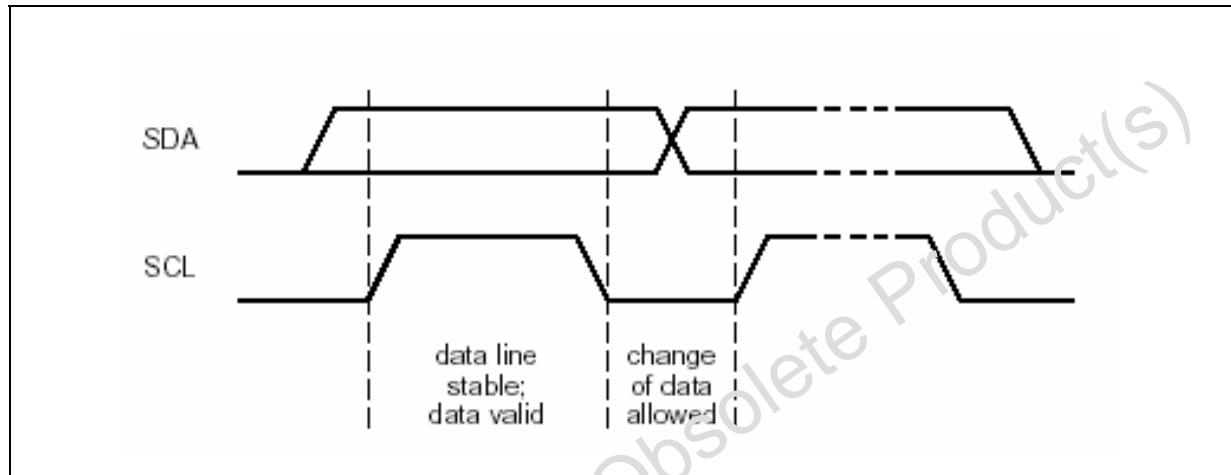

**Figure 6.** Timing diagram on I<sup>2</sup>C Bus

## 7.6 Byte format

Every byte transferred to the SDA line must contain 8 bits. Each byte must be followed by an acknowledge bit. The MSB is transferred first. One data bit is transferred during each clock pulse. The data on the SDA line must remain stable during the HIGH period of the clock pulse. Any change in the SDA line at this time will be interpreted as a control signal.

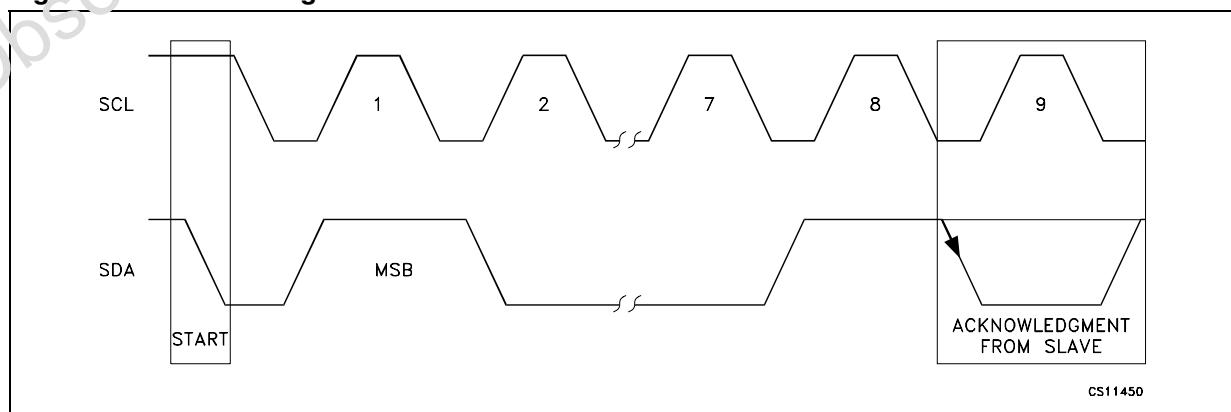

**Figure 7. Bit transfer**

## 7.7 Acknowledge

The master ( $\mu$ P) puts a resistive HIGH level on the SDA line during the acknowledge clock pulse (see [Figure 9](#)). The peripheral (STCF03I) that acknowledges has to pull-down (LOW) the SDA line during the acknowledge clock pulse, so that the SDA line is stable LOW during this clock pulse. The peripheral which has been addressed has to generate an acknowledge pulse after the reception of each byte, otherwise the SDA line remains at the HIGH level during the ninth clock pulse duration. In this case, the master transmitter can generate the STOP information in order to abort the transfer.

**Figure 8 Acknowledge on I<sup>2</sup>C bus**

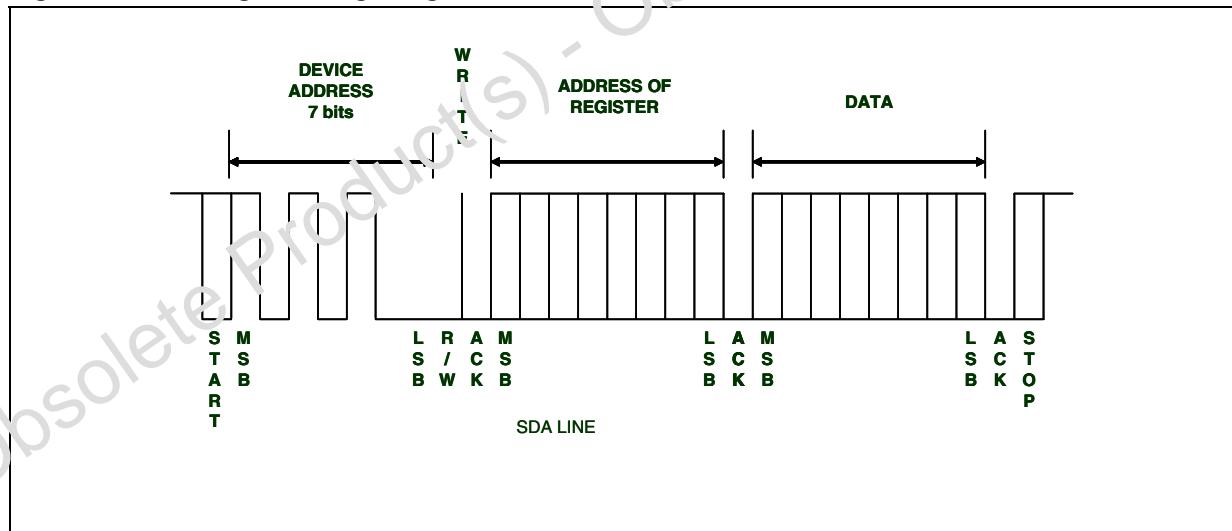

**Table 8.** Interface protocol

	Device address + R/W bit								Register address								Data									
	7	6	5	4	3	2	1	0	7	6	5	4	3	2	1	0	7	6	5	4	3	2	1	0		
S T A R T	M S B			L S B	R W	A C K	M S B									L S B	A C K	M S B						L S B	A C K	S T O P

## 7.8 Writing to a single register

Writing to a single register starts with a START bit followed by the 7 bit device address of STCF03I. The 8<sup>th</sup> bit is the R/W bit, which is 0 in this case. R/W = 1 means a reading operation. Then the master waits for an acknowledge from STCF03I. Then the 8 bit address of register is sent to STCF03I. It is also followed by an acknowledge pulse. The last transmitted byte is the data that is going to be written to the register. It is again followed by an acknowledge pulse from STCF03I. The master then generates a STOP bit and the communication is over. See [Figure 9](#) below.

**Figure 9.** Writing to a single register

## 7.9 Interface protocol

The interface protocol is composed of ([Table 8](#)):

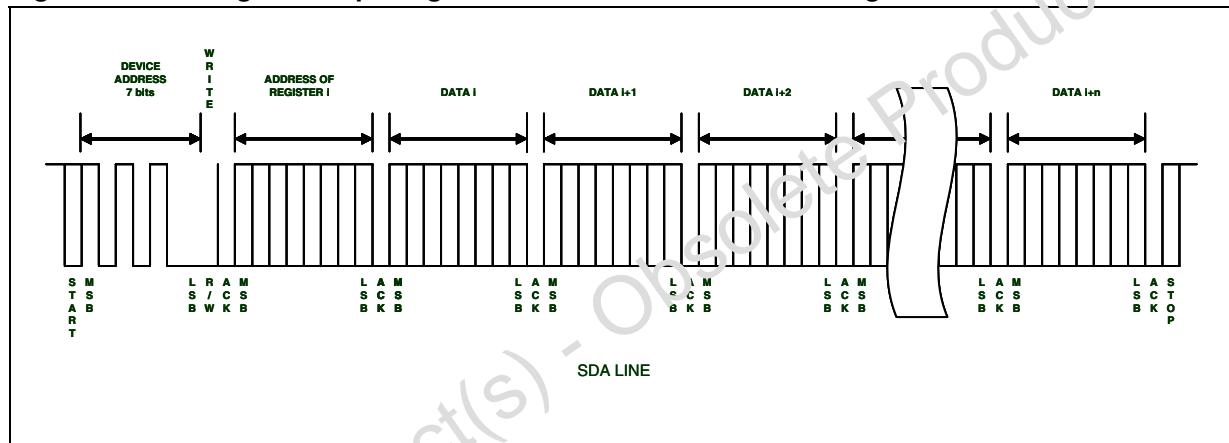

- A start condition (START)
- A Device address + R/W bit (read =1 / write =0)
- A Register address byte
- A sequence of data n\* (1 byte + acknowledge)
- A stop condition (STOP)

The register address byte determines the first register in which the read or write operation takes place. When the read or write operation is finished, the register address is automatically increased.

## 7.10 Writing to multiple registers with incremental addressing

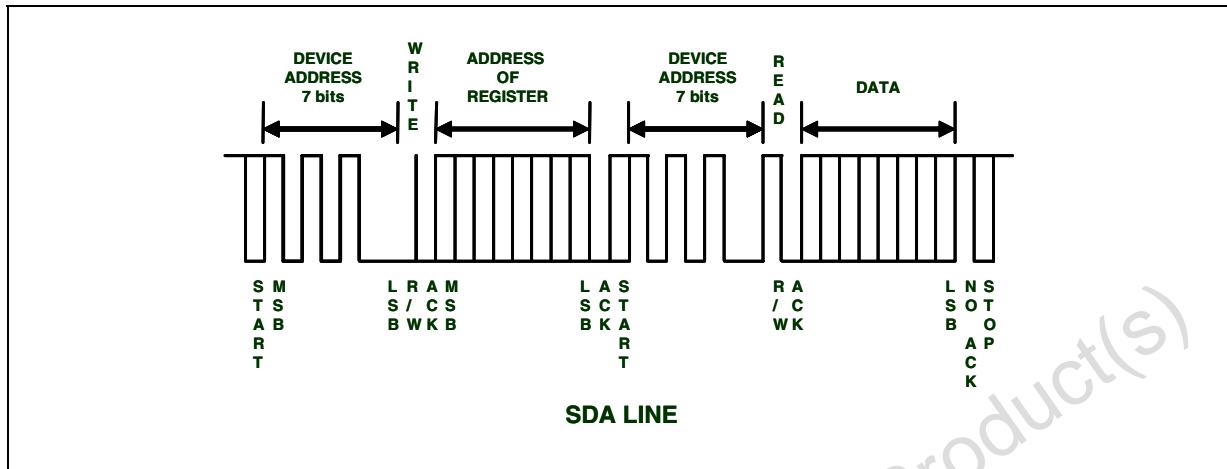

It would be unpractical to send several times the device address and the address of the register when writing to multiple registers. STCF03I supports writing to multiple registers with incremental addressing. When data is written to a register, the address register is automatically increased, so the next data can be sent without sending the device address and the register address again. See [Figure 10](#) below.

**Figure 10. Writing to multiple registers with incremental addressing**

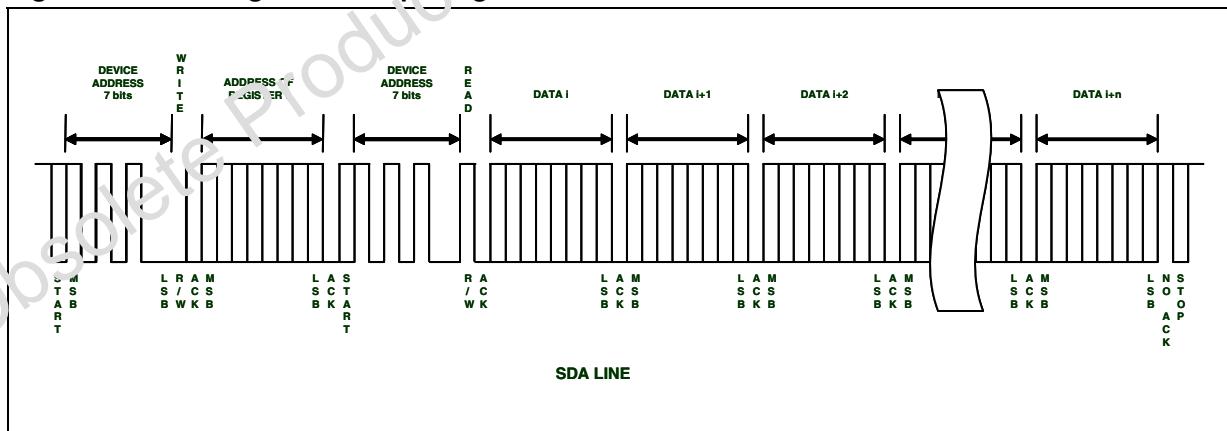

## 7.11 Reading from a single register

The reading operation starts with a START bit followed by the 7 bit device address of STCF03I. The 8<sup>th</sup> bit is the R/W bit, which is 0 in this case. STCF03I confirms the receiving of the address + R/W bit by an acknowledge pulse. The address of the register which should be read is sent afterwards and confirmed again by an acknowledge pulse of STCF03I again. Then the master generates a START bit again and sends the device address followed by the R/W bit, which is 1 now. STCF03I confirms the receiving of the address + R/W bit by an acknowledge pulse and starts to send the data to the master. No acknowledge pulse from the master is required after receiving the data. Then the master generates a STOP bit to terminate the communication. See [Figure 11](#)

**Figure 11.** Reading from a single register

## 7.12 Reading from multiple registers with incremental addressing

Reading from multiple registers starts in the same way like reading from a single register. As soon as the first register is read, the register address is automatically increased. If the master generates an acknowledge pulse after receiving the data from the first register, then reading of the next register can start immediately without sending the device address and the register address again. The last acknowledge pulse before the STOP bit is not required. See the [Figure 12](#).

**Figure 12.** Reading from multiple registers

## 8 Description of internal registers

**Table 9. I<sup>2</sup>C register mapping function**

Register name	SUB ADDRESS (hex)	Operation
CMD_REG	00	R / W
DIM_REG	01	R / W
AUX_REG	02	R / W
STAT_REG	03	R only

**Table 10. Command register**

CMD_REG (write mode)	MSB							LSB
SUB ADD=00	PWR_ON	TRIG_EN	TCH_ON	NTC_ON	FTIM_3	FTIM_2	FTIM_1	FTIM_0
Power ON RESET Value	0	0	0	0	0	0	0	0

### 8.1 PWR\_ON

When set, it activates all analog and power internal blocks including the NTC supporting circuit, and the device is ready to operate (ready mode). As long as PWR\_ON=0, only the I<sup>2</sup>C interface is active, minimizing Stand-by Mode power consumption.

### 8.2 TRIG\_EN

This bit is AND-ed with the TRIG pin to generate the internal signal FL\_ON that activates flash mode. By this way, both soft-triggering and hard-triggering of the flash are made possible. If soft-triggering (through I<sup>2</sup>C) is chosen, the TRIG pin is not used and must be kept HIGH (VI). If hard-triggering is chosen, then the TRIG pin has to be connected to a μP I/O devoted to flash timing control, and the TRIG\_EN bit must be set in advance. Both triggering modes can benefit of the internal flash time counter, that uses the TRIG\_EN bit and can work either as a safety shut-down timer or as a flash duration timer. Flash mode can start only if PWR\_ON=1. LED current is controlled by the value set by the FDIM\_0~3 of the DIM\_REG.

### 8.3 TCH\_ON

When set from ready mode, the STCF03I enters torch mode. The LED current is controlled by the value set by the TDIM\_0~3 of the DIM\_REG.

### 8.4 NTC\_ON

When the NTC\_ON bit is set to HIGH and the device is in ready mode, then the comparators that monitor the LED temperature are activated. NTC-related blocks are always active regardless of this bit in torch mode and flash mode.

## 8.5 FTIM\_0~3

This 4-bits register defines the maximum flash duration. It is intended to limit the energy dissipated by the LED to a maximum safe value or to leave to the STCF03I the control of the flash duration during normal operation. Values from 0~15 correspond to 0~1.5 s (100 ms steps). The timing accuracy is related to the internal oscillator frequency that clocks the flash time counter (+/-20%, TBD). Entering flash mode (either by soft or hard triggering) activates the flash time counter, which begins counting down from the value loaded in the F\_TIM register. When the counter reaches zero, flash mode is stopped by resetting TRIG\_EN bit, and simultaneously the ATN pin is set to true (LOW) to alert the  $\mu$ P that the maximum time has been reached. FTIM value remains unaltered at the end of the count.

**Table 11. Dimming register**

DIM_REG (write mode)	MSB							LSB
SUB ADD=01	TDIM_3	TDIM_2	TDIM_1	TDIM_0	FDIM_3	FDIM_2	FDIM_1	FDIM_0
Power ON, SHUTDOWN MODE RESET Value	0	0	0	0	0	0	0	0

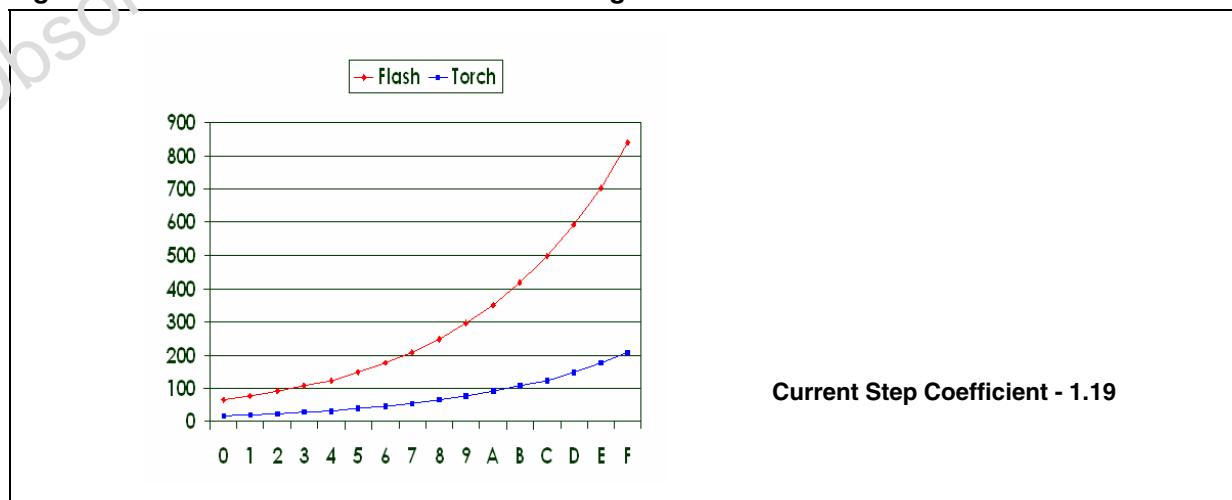

## 8.6 TDIM\_0~3

These 4 bits define the LED current in torch mode with 16 values fitting an exponential law. Max torch current value is 25% of max flash current. ([Figure 13](#))

## 8.7 FDIM\_0~3

These 4 bits define the LED current in flash mode with 16 values fitting an exponential law. The max value of the current is set by the external resistors  $R_{FL}$  and  $R_{TR}$ . ([Figure 13](#))

**Figure 13. Flash and Torch current vs. dimming value**

Note: LED current values refer to  $R_{FL}=0.27\ \Omega$ ,  $R_{TR}=1.8\ \Omega$

**Table 12. Auxiliary register**

AUX_REG (write mode)	MSB							LSB

Power ON, SHUTDOWN MODE RESET Value	0	0	0	0	0	0	0	0

## 8.8 AUXI\_0~3

This 4 bits register defines the AUX LED current from 0 to 20 mA. See AUX LED dimming table for reference. Loading any value between 1 and 15 also starts the AUX LED current source timer, if enabled. The AUX LED current source is active only in ready mode, and is deactivated in any other mode.

## 8.9 AUXT\_0~3

This 4 bit register controls the timer that defines the ON-time of the AUX LED current source. ON-time starts when the AUXI register is loaded with any value other than zero, and stops after the time defined in the AUXT register. Values from 1 to 14 of the AUXT register correspond to an ON-time of the AUX LED ranging from 100 to 1400 ms in 100 ms steps. The value 15 puts the AUX LED to the continuous light mode. The activation/deactivation of the AUX LED current source is controlled using only the AUXI register.

**Table 13. Auxiliary LED dimming table<sup>(1)</sup>**

Power ON, SHUTDOWN MODE RESET Value	0	0	0	0	0	0	0	0

## 8.10 F\_RUN

This bit is kept HIGH by the STCF03I during flash mode. By checking this bit, the µP can verify if the flash mode is running or has been terminated by the time counter.

## 8.11 LED\_F

This bit is set by the STCF03I when the voltage seen on the LED pin is  $V_{REF2} > 5.3$  V during a torch or flash operation. This condition can be caused by an open LED, indicating a LED failure. The device automatically goes into Ready mode to avoid damage. Internal high frequency filtering avoids false detections. This bit is reset by the STCF03I following a read operation of the STAT\_REG.

## 8.12 NTC\_W

This bit is set HIGH by the STCF03I and the ATN pin is pulled down, when the voltage seen on the pin Rx exceeds  $V_{REF4} = 0.56$  V. This threshold corresponds to a warning temperature value at the LED measured by the NTC. The device is still operating, but a warning is sent to the µP. This bit is reset by the STCF03I following a read operation of the STAT\_REG.

## 8.13 NTC\_H

This bit is set HIGH by the STCF03I and the ATN pin is pulled down, when the voltage seen on the pin Rx exceeds  $V_{REF5}$ . This threshold (1.2 V) corresponds to an excess temperature value at the LED measured by the NTC. The device is put in ready mode to avoid damaging the LED. This bit is reset by the STCF03I following a read operation of the STAT\_REG.

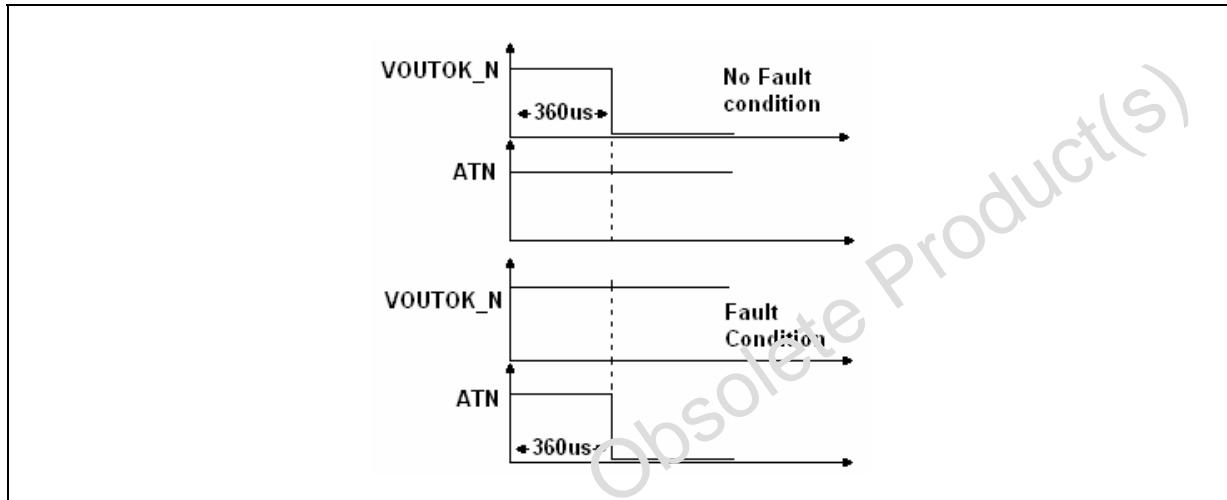

## 8.14 OT\_F

This bit is set HIGH by the STCF03I and the ATN pin is pulled down, when the chip over-temperature protection ( $\sim 140^\circ\text{C}$ ) has put the device in ready mode. This bit is reset by the STCF03I following a read operation of the STAT\_REG.

## 8.15 VOUTOK\_N

This bit is set by the STCF03I. It is used to protect the device, if the output is shorted. The VOUTOK\_N bit is set to HIGH at the start-up. Then a current generator of 20 mA charges the output capacitor for 360  $\mu$ s typ. and it detects when the output capacitor reaches 100 mV. If this threshold is reached the bit is set to LOW. If the output is shorted to ground or the LED is shorted, this threshold is never reached: the bit stays HIGH, ATN pin is pulled down and the device will not start. This bit is reset following a read operation of the STAT\_REG

**Figure 14.** VOUTOK\_N behavior

**Table 16.** Status register details

Bit Name	F_RUN (STAT_REG)	LED_F (STAT_REG)	NTC_W (STAT_REG)	NTC_H (STAT_REG)	OT_F (STAT_REG)	VOUTOK_N (STAT_REG)
<b>Default value</b>	0	0	0	0	0	0
<b>Latched<sup>(1)</sup></b>	NO	YES	YES	YES	YES	YES
<b>Forces Ready mode when set</b>	NO	YES	NO	YES	YES	YES
<b>Sets ATN LOW when set</b>	NO	YES	YES	YES	YES	YES

1. YES means that the bit is set by internal signals and is reset to default by an I<sup>2</sup>C read operation of STAT\_REG NO means that the bit is set and reset by internal signals in real-time.

## 9 Detailed description

### 9.1 PowerON reset

This mode is initiated by applying a supply voltage above the VPW\_ON RESET threshold value. An internal timing (~1 µs) defines the duration of this status. The logic blocks are powered, but the device doesn't respond to any input. The registers are reset to their default values, the ATN and SDA pins are in high-Z, and the I<sup>2</sup>C slave address is internally set by reading the ADD pin configuration. After the internally defined time has elapsed, the STCF03I automatically enters the Stand-by mode.

### 9.2 Shutdown

In this mode, only the I<sup>2</sup>C interface is alive, accepting I<sup>2</sup>C commands and register settings. The device enters this mode: automatically from power ON reset status; by resetting the PWR\_ON bit from other operation modes. Power consumption is at the minimum (1 µA typ).

### 9.3 Ready mode

In this mode all internal blocks are turned ON, but the DC/DC converter is disabled and the white LED is disconnected. The NTC circuit can be activated to monitor the temperature of the LED and I<sup>2</sup>C commands and register settings are allowed to be executed immediately. Only in this mode the auxiliary LED is operational and can be turned ON and set at the desired brightness using the AUX REGISTER. The device enters this mode: from stand-by by setting the PWR\_ON bit; from flash operation by resetting the TRIG pin or the TRIG\_EN bit or automatically from flash operation when the time counter reaches zero; from torch operation by resetting the TCH\_ON bit. The device automatically enters this mode also when an overload or an abnormal condition has been detected during flash or torch operation ([Table 16: Status register details](#):).

### 9.4 Single or multiple Flash using external (µP) temporization

To avoid the I<sup>2</sup>C bus time latency, it is recommended to use the dedicated TRIG pin to define the flash duration (hard-triggering). The TRIG\_EN bit of CMD\_REG should be set before starting each flash operation, because it could have been reset automatically in the previous flash operation. The flash duration is determined by the pulse length that drives the TRIG pin. As soon as the flash is activated, the system needs typically 1.2 ms to ramp up the output current on the Power LED. The internal time counter will time-out flash operation and keep the LED dissipated energy within safe limits in case of Software deadlock; FTIM register has to be set first, either in stand-by or in ready mode. Multiple flashes are possible by strobing the TRIG pin. Time out counter will cumulate every flash on-time until the defined time out is reached unless it is reloaded by updating the CMD\_REG. After a single or multiple flash operations are timed-out, the device automatically goes into Ready mode by resetting the TRIG\_EN bit, and also resets the F\_RUN bit. The ATN pin is pulled down to inform the µP that the STAT\_REG has been updated.

## 9.5 External ( $\mu$ P) temporization using TRIG\_EN bit

Even if it is possible, it is not recommended to use the TRIG\_EN bit to start and stop the flash operation, because of I<sup>2</sup>C bus latencies: this would result in inaccurate flash timing. Nevertheless, if this operation mode is chosen, the TRIG pin has to be kept High (logic level or wired to V<sub>BAT</sub>), leaving the whole flash control to the I<sup>2</sup>C bus. Also in this operation mode the time counter will time-out flash operation and keep the energy dissipated by the LED within safe limits in case of SW deadlock.

## 9.6 Single Flash using internal temporization

Flash triggering can be obtained either by TRIG pin (hard-triggering) or by I<sup>2</sup>C commands (soft-triggering). The first solution is recommended for an accurate start time, while the second is less accurate because of the I<sup>2</sup>C bus time latency. Stop time is defined by the STCF03I internal temporization and its accuracy is determined by the internal oscillator. For hard-triggering, it is necessary to set the TRIG\_EN bit in advance. For soft-triggering, the TRIG pin has to be kept High (logic level or wired to V<sub>BAT</sub>) and the flash can be started by setting the FTIM and the TRIG\_EN through I<sup>2</sup>C (both are located in the CMD REG). There is a delay time between the moment the flash is triggered and when it appears. This delay is caused by the time necessary to charge up the output capacitor, which is around 1.2 ms depending on battery voltage and output current value. Once triggered, the flash operation will be stopped when the time counter reaches zero. As soon as the flash is finished, the F\_RUN bit is reset, the ATN pin is pulled down for 11  $\mu$ s to inform the  $\mu$ P that the STAT\_REG has been updated and the device goes back to Ready mode. If it is necessary to make a flash longer than the internal timer allows or a continuous flash, then the FTIM must be reloaded through I<sup>2</sup>C bus every time, before the internal timer reaches zero. For example: To get a continuous flash, set FTIM to 1.5 s and every 1 s reload the CMD\_REG.

## 9.7 Multiple Flash using internal temporization

This operation has to be processed as a sequence of single flashes using internal temporization starting from hard or soft triggering. Since the TRIG\_EN bit is reset at the end of each flash, it is necessary to reload the CMD\_REG to start the next one.

## 11 Package mechanical data

In order to meet environmental requirements, ST offers these devices in ECOPACK® packages. These packages have a lead-free second level interconnect. The category of second level interconnect is marked on the package and on the inner box label, in compliance with JEDEC Standard JESD97. The maximum ratings related to soldering conditions are also marked on the inner box label. ECOPACK is an ST trademark. ECOPACK specifications are available at: [www.st.com](http://www.st.com)
